

RAS Cryptosystem								
Pick two large primes p and q . Let $n = pq$. Encryption key (n, e) and								
decryption key (n, d) are selected such that								
(1) $\gcd(e,(p-1)(q-1))=1$								
$(2) ed \equiv 1 \pmod{(p-1)(q-1)}$								
RSA encryption: $C = M^e \mod n$; RSA decryption: $M = C^d \mod n$. Why?								
According to (1) , the inverse d exists. According to (2) , there exists an								
integer k such that								
de=1+k(p-1)(q-1).								
It follows that $C^d \equiv (M^e)^d = M^{de} = M^{1+k(p-1)(q-1)} \pmod{n}$.								
Assuming that $\gcd(M,p)=\gcd(M,q)=1$, we have $M^{p-1}\equiv 1\pmod p$								
and $M^{q-1} \equiv 1 \pmod{q}$. (see Theorem 3 in Section 4.4) SUSTech thomason	d d							
According to (1), the inverse d exists. According to (2), there exists an integer k such that $de = 1 + k(p-1)(q-1).$								
$de = 1 + k(p-1)(q-1).$ It follows that $C^d \equiv (M^e)^d = M^{de} = M^{1+k(p-1)(q-1)} \pmod{n}$.								
Assuming that $gcd(M, p) = gcd(M, q) = 1$, we have $M^{p-1} \equiv 1 \pmod{p}$ and $M^{q-1} \equiv 1 \pmod{q}$.)							
$C^d \equiv M \cdot (M^{p-1})^{k(q-1)} \equiv M \cdot 1 = M \pmod{p}$								
$C^d \equiv M \cdot (M^{q-1})^{k(p-1)} \equiv M \cdot 1 = M \pmod{q}.$								
Personal modern at 1 we have								
Because $gcd(p,q)=1$, we have								
$C^d \equiv M \; (mod \; pq).$								
This basically implies that								
$M = C^d \mod n$	d d

Diffie-Hellman Key Exchange Protocol Two parties exchange a secret key over an insecure communications channel without having shared any information in the past. Diffie-Hellman Key Exchange Protocol Before introducing the protocol: **Definition:** A primitive root modulo a prime p is an integer r in Z_p such that every nonzero element of Z_p is a power of r. Example: Whether 2 is a primitive root modulo 11? When we compute the powers of 2 in Z_{11} , we obtain $2^1=2$, $2^2=4$, $2^3=8$, $2^4=5$, $2^5=10$, $2^6=9$, $2^7=7$, $2^8=3$, $2^9=6$, $2^{10}=1$. Because every element of Z_{11} is a power of 2, 2 is a primitive root of 11 Suppose that Alice and Bob want to share a common key. Consider Z_p . (1) Alice and Bob agree to use a prime p and a primitive root a of p. (2) Alice chooses a secret integer k_1 and sends $a^{k_1} \mod p$ to Bob. (3) Bob chooses a secret integer k_2 and sends $a^{k_2} \mod p$ to Alice. (4) Alice computes $(a^{k_2})^{k_1} \mod p$. (5) Bob computes $(a^{k_1})^{k_2} \mod p$. Alice and Bob have computed their shared key: $(a^{k_2})^{k_1} \mod p = (a^{k_1})^{k_2} \mod p.$ • Public information: p, a, a^{k_1} mod p, and a^{k_2} mod p• Secret: k_1 , k_2 , $(a^{k_2})^{k_1}$ mod $p = (a^{k_1})^{k_2}$ mod pNote that it is very hard to determine k_1 with a, p, and $a^{k_1} \mod p$. Blockchain A blockchain is a decentralized, distributed, and oftentimes public, digital ledger consisting of records called blocks that are used to record transactions (or data) across many computers. Time Stamp Nonce Time Stamp Nonce Merkle Root Any involved block cannot be altered retroactively, without the alteration of all subsequent blocks. Mining Given a set of transactions, generate a new block: Time Stamp Nonce Time Stamp Nonce Time Stamp Nonce Merkle Root Merkle Root Merkle Root Proof of Work: Take the current block's header, guess the nonce such that the hash of the header (SHA-256) smaller than a target value. The target can be changed to adjust the difficulty of mining. Transaction data cannot be tampered: • If transaction data is tampered, then the Merkle root needs to be changed; • Then nonce needs to be changed. (very difficult!) • Even if a nonce is found, the hash of the header is changed • The header of the subsequent block also needs to be changed. SUSTech Gouthers of Biolence Technology ...
